What is Fluid model?

In CSS, a Fluid Layout, also sometimes referred to as a liquid layout, is a design approach that prioritizes flexibility and responsiveness across different screen sizes. It contrasts with fixed layouts that have a set width and may appear distorted on various devices.

Creating a fluid layout:

Here's a general process for creating a fluid layout:

1. Define a base font size and line height : This sets the foundation for responsive typography.

2. Use percentages for widths and margins : Set the width of your container element (often the body) to 100% and define element widths and margins as percentages relative to that container

3. Utilize media queries : For more granular use media queries to adjust styles for specific screen sizes or device orientation .
